This paper establishes a revenue model for distributed energy storage systems to analyze and compare the impact of transitioning from a peak-valley electricity price condition to a deep-valley electricity price condition on the revenue generated by. The revenue potential of energy storage is often undervalued. Investors could adjust their evaluation approach to get a true estimate—improving profitability and supporting sustainability goals. As the global build-out of renewable energy sources continues at pace, grids are seeing unprecedented. These benchmarks help measure progress toward goals for reducing solar electricity costs and guide SETO research and development programs. A minimum price spread of around \$30 to \$50 per megawatt-hour (MWh) is typically necessary to cover. The profit model of industrial and commercial energy storage is peak-valley arbitrage, that is, a low electricity price is used to charge in the trough of electricity consumption, and discharge in the peak of electricity consumption to industrial and commercial users, users can save electricity. As electricity prices fluctuate daily, battery systems enable operators to store excess solar energy during low-demand periods and sell it when prices spike. For instance, California's solar farms now achieve 20–30% higher profitability using lithium-ion batteries to shift energy delivery to peak. The models are developed for the pure photovoltaic system without storage, the photovoltaic and energy storage hybrid system, and the hybrid system considering SOH (State of Health) variation of the battery during the lifecycle. The revenue variations using these models under different pricing.
